Monotone Systems approach in Inductive Learning

Peeter Roosmann, Leo Võhandu, Rein Kuusik, Tarvo Treier, and Grete Lind

Abstract—In this paper we present a new approach for machine learning (ML) task solution based on Monotone Systems Theory, an inductive learning algorithm named by the authors as MOnSIL (MONotone Systems in Inductive Learning). It has some advantages compared with several ML algorithms as rules overlapping, it can use several pruning techniques etc. The algorithm MOnSIL usually produces more rules than other ML algorithms and it means that it would be more work-consuming than others, but as our experiments show, MOnSIL works quite effectively.

In the paper we define also main terms of monotone systems theory, describe how to create monotone system to the data table and describe main advantages of the monotone systems approach. We also prove that concept description found by MOnSIL is complete and consistent, explain algorithm’s main steps on examples and discuss results of experiments comparing MOnSIL effectiveness with well-known ID3.

Keywords—Inductive learning, Machine learning, Machine learning algorithm, Monotone systems theory.

I. INTRODUCTION

In the domain of inductive learning there are many different algorithms in use (AQ, CN2, CART, ID3 and Assistant with their derivatives etc). Such a variety of algorithms shows that in the domain of inductive learning there are different problems which are hard to solve by one specific algorithm.

In the inductive learning environment we have problem how to manage large example sets with an unknown complicated structure. From our experience we can say that monotone systems algorithms have been very efficient in ordering large data tables and for finding regularities from these [1]-[4]. We try to use techniques that have been successful in data analysis in the inductive learning field.

This paper describes very shortly the underlying theory and describes also how to use monotone systems theory in inductive learning. A new learning algorithm is presented and discussed. In the end of paper we make a comparison of the effectiveness of our algorithm with ID3 on the well-known King-Rook-King task by D. Michie [5].

II. DEFINITIONS

We mainly originate from the notions of the article [6].

The set of objects \( X=\{x_1,\ldots,x_k\} \) can be described with attributes \( t_1,\ldots,t_M \) so that every object \( x_i \) can be described as a tuple

\[ x_i=(t_1(x_i),\ldots,t_M(x_i))=(x_{i1},\ldots,x_{iM}). \]

For each attribute \( t_j \) there exists a finite set of values \( A_j \) \( (1\leq j \leq M) \). So the attribute value \( x_{ij} \) of the object \( x_i \) belongs to the set \( A_j \)

\[ x_{ij}=t_j(x_i) \in A_j. \]

Classes \( C_1,\ldots,C_k \) are subsets of \( X \) such that

\[ C_1\cup\ldots\cup C_k \forall \forall j \exists i: C_j \cap C_j = \emptyset. \]

The class value of the object \( x \in X \) is \( c_j \) if \( x \in C_j \). Let us denote the set of class values as

\[ C=\{c_1,\ldots,c_k\}. \]

A learning example \( e_i \) is a tuple created from an object \( x_i \) and its class value

\[ e_i=(x_i,c_i)=((t_1(x_i),\ldots,t_M(x_i)),c_i)=(x_{i1},\ldots,x_{iM},c_i). \]

Let us denote the set of examples \( E \) as

\[ E=\{e_1,\ldots,e_n\}. \]

Let us denote the set of examples of class \( C_j \) as

\[ E_j=\{e|e=(x,c), x \in C_j, C_j \subseteq C\}. \]

The positive example \( e_j \) of the class \( C_j \) is an example which belongs to the set \( E_j \), i.e.

\[ e_j \in E_j \subseteq E. \]

The negative example \( e_j \) of the class \( C_j \) is an example which does not belong to the set \( E_j \), i.e.

\[ e_j \notin E_j \subseteq E. \]

The majority class of set \( E \) is the class with the largest number of examples.

Function \( d \) which does map according to every element of the set \( X \) a class value \( c_j \) is called a concept

\[ d:X \rightarrow C; d(x_i)=c_j \Leftrightarrow x_i \in C_j. \]

In inductive learning the learning system should on the base of the learning examples find a concept description \( D \) which
maps a class value for any object of the set X (not only for objects from the example set) D:X→C. Consequently the inductive learning system should (in ideal case) find on the base of learning examples such concept description D which maps to every object the same class value as a concept d
∀x∈X, D(x)=d(x).

The (concept) description is the set of classification rules D={r₁,...,rₙ}.

A classification rule (decision rule) is an implication where a condition is a complex and a conclusion part is a class name:

rᵢ = “Comᵢ => cᵢ”
or
rᵢ = “if Comᵢ then cᵢ”
or
rᵢ=(Comᵢ,cᵢ).

Complex Comᵢ is a tuple of selectors Selᵢk (k=1,...,M)
Comᵢ=(Selᵢ₁,...,Selᵢₘ).

Selector Selᵢ is a subset of the set of values of the attribute tᵢ
Selᵢ⊆Aᵢ.

Description D maps a class value cᵢ for an object xᵢ if it contains a classification rule rᵢ which maps a class value cᵢ for the object xᵢ
∃rᵢ∈D, rᵢ(xᵢ)=cᵢ = D(xᵢ)=cᵢ.

Rule rᵢ=(Comᵢ,cᵢ) maps a class value cᵢ for an object xᵢ if its complex Comᵢ covers the object xᵢ
rᵢ=(Comᵢ,cᵢ), cover(Comᵢ,xᵢ) ⇒ rᵢ(xᵢ)=cᵢ.

Complex Comᵢ covers an object xᵢ if all its selectors Selᵢk cover this object
∀k, 1≤k≤M, cover(Selᵢk,xᵢ) ⇒ cover(Comᵢ,xᵢ).

Selector Selᵢ covers an object xᵢ if the value of the attribute tᵢ of the object xᵢ is in the set Selᵢk
∀j, 1≤j≤M, xᵢ∈Selᵢk ⇒ cover(Selᵢk,xᵢ).

Description D is consistent on the set X⊆X if all its rules map the same class value for any object x∈X
∀rᵢ,rⱼ∈D, x∈X', X'⊆X, cover(Comᵢ,x), cover(Comⱼ,x) ⇒ rᵢ(x)=rⱼ(x).

Description D is complete on the set X⊆X if for each object x∈X there exists at least one rule so that its complex covers this object
∀x∈X', x′⊆X, ∃rᵢ∈D, cover(Comᵢ,x).

The inductive learning algorithms have to allow us to find descriptions that are at the same time both consistent and complete.

III. MONOTONE SYSTEMS BASED INDUCTIVE LEARNING ALGORITHMS

A lot of initial data and complicated inner structures of objects are common difficulties for data analysis, data mining, graph theory etc. This is true also for learning from examples. In the well-ordering of large and confused data sets the use of the algorithms of theory of monotone systems has been very successful and we try to use these ideas in the inductive learning field as well.

In [7] L. Võhandu described a possibility for quick data processing methodology, which uses the idea of building weakly monotone systems on data tables, using empirical frequencies of discrete attributes’ values. The main mechanism of using algorithms of the theory of monotone systems is so called frequency transformation. It means that frequencies of every attribute value are calculated and values in the data table (corresponding to the objects) are replaced with their corresponding frequencies over the data table. Such a transformation enables one to estimate the degree of systematic conformity of objects on the set of learning examples. Both, objects with high conformity (for finding general rules) and objects with low conformity (for discovering exceptions and noise) are substantial in inductive learning.

Some of the attributes are more important in learning from examples. The estimation of importance of attributes is easy to do using the frequency transformation.

The frequency transformation and conformity measure guarantees a simple way to estimate the typicality of objects. The theory of monotone systems allows one to work with the tables of frequencies instead of real data tables. The computing with much smaller tables of frequencies is a lot quicker than with full data tables, although all the important information for learning is easily accessible.

A. Main concepts of theory of monotone system

We present the main concepts of the theory of monotone systems by J. Mullan [8].

Let a finite set X={x₁,...,xₙ} and a function πₓ on it which maps to each element x∈X a certain nonnegative number (weight) πₓ(x), be given. This function πₓ is called a weight function if it is defined on any subset X′⊆X; the number πₓ(x) is called a weight of element x on X′.

A set X with a weight function πₓ is called a system and is denoted by S=(X,πₓ).

The system S=(X,πₓ) where X′⊆X is called a subsystem of the system S=(X,πₓ).

The system S=(X,πₓ) is called monotone (more exactly weakly monotone) if in the case of any x we have
∀X′⊆X; ∀x∈X′\{y}, (y∈X): πₓ(x)=πₓ(y)≤πₓ(x).

Function Q that is mapping to every subset X′⊆X of a monotone system S a nonnegative number Q(X′)=min πₓ(x) is called an objective function.

The subsystem S′=(W, πₙ) of the monotone system S=(X,πₓ) with the property that the objective function obtains a maximal value Q(W)=max Q(X′)=max min πₓ(x) on it is called a kernel of the monotone system S; respectively the value Q(W) is called a measure of the kernel quality. For a kernel the following relation is valid ∀X′⊆X: Q(X′)≤Q(W).

To use the method of monotone systems in practice we have to fulfill two conditions:
1) There has to exist a weight function πₓ(x) which will give a measure of influence for every element x∈X;
2) There have to be rules to recompute the weights of the elements of the system S=(X,πₓ) in case there is a change
in the weight of one element \(x \in X\).

These two conditions give a lot of freedom to choose the weight functions and create formal rules of weight changes in the system \(S=(X, \pi_X)\). The only constraint we have to keep in mind is that the rules and the weight function have to be compatible in the sense that after eliminating all elements \(x\) from the system \(S\) the final weights of \(x \in X\) must be equal to zero.

Kernels of a monotone system built on the empirical system create a nice picture of the inner structure of the given empirical system. We just mention that in general case one orders all objects of the system \(S=(X, \pi_X)\) by eliminating in \(N\) steps all objects using the weight monotonicity condition. On every step we eliminate the object with minimal weight value and recalculate weight of all other remaining objects.

### B. Algorithm MONSA

To find all kernels of a monotone system a very effective polynomial time algorithm named MONSA (MONotone Systems Algorithm) was created [2], see also [3], [9].

In order to describe that algorithm we use an additional concept of an intersection.

The **intersection** \(I\) of the set \(X\) is any set of attribute values which belong simultaneously to all objects \(x \in X\):

\[
I = \{x_i : \forall i, x_i \in X\}
\]

The intersection \(H\) describes on the set \(X\) a subset \(X'_H\)

\[
X'_H = \{x_j : \forall j, x_j \in H\}, \quad X'_H \subseteq X
\]

In [2] it is proved that the subset \(X'_H \subseteq X\) extracted by the algorithm MONSA is a kernel \(S'=(X'_H, \pi_{X'_H})\) of the system \(S=(X, \pi_X)\).

In order to use the monotone system method for inductive learning we use a very simple weight function connected to the frequencies of system element attribute values. To build a monotone system on the set of discrete data \(X\) we first calculate the frequency table \(F: F=[|Z|]_{j=1,\ldots,M; k=1,\ldots,|A|}\), where \(f_k=|Z_k|, Z_k=\{x | x_k=k\}\).

After that we define the weight of the element \(x_i\) on the set \(X\) in the system \(S=(X, \pi_X)\) as \(\pi(x_i)=f_k\).

The system with a weight function \(\pi(x_i)=f_k\) is weakly monotone since

\[
\forall i, \forall j, \forall k: |Z_k| \leq |Z_k| \quad \text{if} \quad i \text{ is general, the elimination of an object can only lessen the frequencies and weights of other objects in the system} \ S=(X, \pi_X).
\]

It is easy to see that the concept of intersection is similar to the concept of complex, so it would be useful for learning from examples.

The algorithm for learning from examples built up on the algorithm MONSA follows:

**Initialize description** \(D=\{\}\)

**FOR** \(j=1\) **TO** \(K\) (\(K\) - number of classes)

- **Let complex** \(\text{Com}=(A_1, \ldots, A_M)\) i.e. \(\forall \text{Sel}_i = A_i\)
- **Find** \(E_i = \{e | e \in C_j\}\)
- **Call procedure** **MONSA**(Com, C_j, E_i)

**NEXT j**

**PROCEDURE** **MONSA**(Com, Class, X)

- **Find** the frequency table \(F\) on the set \(X\) for all attributes \(t_j\) where \(\text{Sel}_i = A_j\)
- **Find** the minimal value \(f_{\text{min}} = f_{j', k'}\) from the frequency table \(F\)
- **Find** the maximal value \(f_{\text{max}} = f_{j'', k''}\) from the frequency table \(F\)
- **IF** \(f_{\text{min}} = f_{\text{max}}\) **THEN**
  - **Add** the rule \(r=(\text{Com}, \text{Class})\) into the description \(D\)
- **ELSE**
  - **WHILE** \(f_{\text{max}}>f_{\text{min}}>0\) **DO**
    - **Let** \(\text{Sel}_j = k''\)
    - **Call** procedure **MONSA**(Com, Class, X)
    - **Let** \(f_{j', k''} = 0\)
  - **END WHILE**
- **END IF**

**END PROCEDURE**

Description produced via such a simple algorithm is complete, i.e. every example is covered by at least one classification rule. All intersections are created only by the set of examples \(E_j\) of the class \(C_j\). So, it is possible, that there exists another set \(E_j\) (\(\pi\)), such that it has an identical intersection with the one extracted from \(E_j\). Consequently, we cannot declare that the derived description is consistent. There can exist an example which belongs to both classes \(C_j\) and \(C_i\).

In the next section we describe a more powerful algorithm, which generates complete and consistent concept descriptions.

### C. New inductive learning algorithm MONSEL

In the algorithm presented in the section III.B the learning examples are arranged into classes and all intersections (complexes) are derived for every subset. Algorithm MONSIL (MONotone Systems in Inductive Learning) presented in this section works in a reverse direction, i.e. an intersection (complex) is derived first using frequency tables and after that one checks whether all examples covered by it belong to the same class. If it is true, then the classification rule is added into the concept description.

Algorithm MONSIL presents a very comfortable mechanism for extracting kernels of the data table. Using the frequency table intersections are made. If the maximum value of the weight function is equal to the minimum value of the weight function, then a kernel can be extracted [2].

In the algorithm MONSIL we first build the frequency tables in the same way, but the conditions for extracting rules are different. If a complex \(\text{Com}\) which covers only examples of one class \(C_j\) is found, then a classification rule \(r=(\text{Com}, C_j)\) is added into the concept description.

Unlike in the algorithm MONSA the selectors (elements of intersections) in MONSEL are chosen according to the minimal values of the elements of frequency tables. There is no contradiction with the theory of monotone systems, because the condition of extracting a kernel remains the same - the maximal value of the weight function has to be equal to the
minimum value of the weight function. Only the order of
evaluating a kernel will be different.
In the following algorithm we use:
Com for complex;
Sel for selector.

The algorithm MONSIL:
Initialize the complex Com={& Sel_k }
Initialize the description D={} 
Find the frequency table F on set of learning
examples E 
Call procedure MONSIL(Com,F)

The main procedure of the algorithm follows:

PROCEDURE MONSIL(Com,F)
IF ∃ j, ∀ i, cover(Com,x_i): x_i ∈ C_i THEN (i.e. 
if all examples covered by a complex
belong to the same class)
Add a rule r=(Com,c_j) to the description D
ELSE
Find the frequency table F’=||f’_{ij}|| on 
the set of learning examples E 
If f_{ij}=0 then let f’_{ij}=0
Find the minimal value f’_{min}=f’_{j,k'} (over 
all f’_{ij}>0)
Find a new complex Com’ so that Sel_j=k'
and the other selectors Sel_i (j≠j')
are the same as in the complex Com
WHILE f’’_{min}>0 DO
Call procedure MONSIL(Com’,F’)
Let f’’_{j,k'=0}
Find the new minimal value f’’_{min} from 
the frequency table F’ and a new
complex Com’
END WHILE
END IF
END PROCEDURE

Theorem 1. Concept description found by the algorithm
MONSIL is complete - every example is covered by at least one rule.
Proof: Minimal values from the frequency table are searched by the algorithm as long as there are frequencies
greater than zero. The value of the element of the frequency
table is put to zero iff there exists a rule that corresponds to
this subset of examples.
Theorem 2: Concept description found by the algorithm
MONSIL is consistent - all its rules map the true class value
for any example.
Proof: A rule will be added into the description only if 
examples covered by its complex belong to the same class. 
This condition of algorithm excludes all rules, that cover also examples belonging to some other class(es).

D. The first example
In order to demonstrate MONSIL in action the classic J.
R. Quinlan’s example set is used [10]. There are five examples
of class “-” and three examples of class “+”. All examples have three attributes (see Table I):
A_1="Height" with values “short”, “tall”;
A_2="Hair" with values “dark”, “red”, “blond”;
A_3="Eyes" with values “blue”, “brown”.

Table I. The example set (from Quinlan)
<table>
<thead>
<tr>
<th>Height</th>
<th>Hair</th>
<th>Eyes</th>
<th>Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>x_1</td>
<td>short</td>
<td>blond</td>
<td>blue</td>
</tr>
<tr>
<td>x_2</td>
<td>tall</td>
<td>blond</td>
<td>brown</td>
</tr>
<tr>
<td>x_3</td>
<td>tall</td>
<td>red</td>
<td>blue</td>
</tr>
<tr>
<td>x_4</td>
<td>short</td>
<td>dark</td>
<td>blue</td>
</tr>
<tr>
<td>x_5</td>
<td>tall</td>
<td>dark</td>
<td>blue</td>
</tr>
<tr>
<td>x_6</td>
<td>tall</td>
<td>blond</td>
<td>blue</td>
</tr>
<tr>
<td>x_7</td>
<td>tall</td>
<td>dark</td>
<td>brown</td>
</tr>
<tr>
<td>x_8</td>
<td>short</td>
<td>blond</td>
<td>brown</td>
</tr>
</tbody>
</table>

The concept description generated by ID3 (Quinlan [10])
contains four classification rules:
r_1=((Hair="dark")=>(Class="-"));
r_2=((Hair="red")=>(Class="+"));
r_3=((Hair="blond")&Eyes="blue")=>(Class="+"));
r_4=((Hair="blond")&Eyes="brown")=>(Class="-"));

We describe now how MONSIL works on the example set.
We collect all attribute values into one table (Table II) and
count the corresponding frequencies of those values (Table III).

Table II. The attribute values in the frequency table
<table>
<thead>
<tr>
<th>A_1</th>
<th>A_2</th>
<th>A_3</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_1</td>
<td>short</td>
<td>dark</td>
<td>blue</td>
</tr>
<tr>
<td>v_2</td>
<td>tall</td>
<td>red</td>
<td>brown</td>
</tr>
<tr>
<td>v_3</td>
<td>*</td>
<td>blond</td>
<td>*</td>
</tr>
</tbody>
</table>

Table III. The frequency table F_1
<table>
<thead>
<tr>
<th>A_1</th>
<th>A_2</th>
<th>A_3</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_1</td>
<td>3</td>
<td>5</td>
<td>5</td>
</tr>
<tr>
<td>v_2</td>
<td>5</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>v_3</td>
<td>*</td>
<td>4</td>
<td>*</td>
</tr>
</tbody>
</table>

Step 1: We find the minimal value f_{min}=f_2=3 from the
frequency table F_1. Since there is only one example (x_3)
covered by the complex (Hair="red") then the rule
r_2=((Hair="red")=>(Class="+")) will be added into the
description. The value f_2 in the frequency table F_1 will be put
to zero.
Step 2: The new minimal value f_{min}=f_1=1 will be found. If
there are many equal minimal values we take the first one. For
the three examples x_1, x_4, x_6 covered by the complex
(Height="short") the new frequency table is F_2 (see Table IV)
and from here for f_{min}=f_2=1 a new rule r_2=((Height="short"&
Hair="dark") => (Class="-")) will be created. In the frequency
table $F_2$ the value $f_{32}$ will be put to zero.

### Table IV. The frequency table $F_2$ (Height="short")

<table>
<thead>
<tr>
<th></th>
<th>$A_1$</th>
<th>$A_2$</th>
<th>$A_3$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$v_1$</td>
<td>1</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>$v_2$</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>$v_3$</td>
<td>2</td>
<td>*</td>
<td>*</td>
</tr>
</tbody>
</table>

**Step 3:** A new $f_{min}=f_{32}=1$ will be found. Consequently: $r_3=((\text{Height}="\text{short}"&\text{Eyes}="\text{brown}")=>(\text{Class}="-"))$. In the frequency table $F_2$ the value $f_{32}$ will be put to zero.

**Step 4:** The new $f_{min}=f_{32}=2$ will be found. For the examples $x_1$, $x_8$ covered by the complex (Height="short"&Hair="blond") a new frequency table $F_3$ (see Table V) will be created. Here "10" means that in the frequency table $F_2$ the value $f_{32}$ is already zero, consequently the corresponding complex (Height="short"&Hair="blond"&Eyes="brown") is unnecessary – it would be a specification of already found rule $r_3$. The minimal value $f_{min}=f_{31}=1$ of the table $F_3$ will create the rule $r_4=((\text{Height}="\text{short}"&\text{Hair}="\text{blond}"&\text{Eyes}="\text{blue}")=>(\text{Class}="-"))$. In the frequency table $F_2$ the value $f_{32}$ will be put to zero.

### Table V. The frequency table $F_3$ (Height="short"&Hair="blond")

<table>
<thead>
<tr>
<th></th>
<th>$A_1$</th>
<th>$A_2$</th>
<th>$A_3$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$v_1$</td>
<td>1</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>$v_2$</td>
<td>1/0</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>$v_3$</td>
<td>*</td>
<td>*</td>
<td>*</td>
</tr>
</tbody>
</table>

**Step 5:** For the new $f_{min}=f_{31}=2$ (examples $x_1$, $x_8$) in $F_2$ the frequency table $F_4$ (see Table VI) will be created. “Bringing zeros down” from $F_2$ prevents finding complexes (Height="short"&Eyes="blue"&Hair="dark") which is a specification of already found rule $r_3$ and (Height="short"&Eyes="blue"&Hair="blond") which is a repetition of $r_4$. In $F_4$ there is no $f_{min}=0$ therefore in the frequency table $F_2$ the value $f_{31}$ will be put to zero and there is no new $f_{min}=0$ neither. Now we have exhausted all complexes created from the field $f_{31}$ and the value $f_{31}$ in the frequency table $F_1$ will be put to zero.

### Table VI. The frequency table $F_4$ (Height="short"&Eyes="blue")

<table>
<thead>
<tr>
<th></th>
<th>$A_1$</th>
<th>$A_2$</th>
<th>$A_3$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$v_1$</td>
<td>1/0</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>$v_2$</td>
<td>0</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>$v_3$</td>
<td>1/0</td>
<td></td>
<td>*</td>
</tr>
</tbody>
</table>

**Step 6:** The minimal value in $F_1$ is $f_{min}=f_{31}=3$, the new complex is (Hair="dark"), the new examples are $x_4$, $x_5$, $x_7$ and the corresponding frequency table is $F_5$ (see Table VII). Here $f_{31}=f_{min}=3$ means the number of examples in the class "-", consequently $r_5=((\text{Hair}="\text{dark}")=>(\text{Class}="-"))$. The value $f_{31}$ in the frequency table $F_1$ will be put to zero.

### Table VII. The frequency table $F_5$ (Hair="dark")

<table>
<thead>
<tr>
<th></th>
<th>$A_1$</th>
<th>$A_2$</th>
<th>$A_3$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$v_1$</td>
<td>1/0</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>$v_2$</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>$v_3$</td>
<td>*</td>
<td>*</td>
<td>*</td>
</tr>
</tbody>
</table>

**Step 7:** We will choose a new minimal nonzero in the table $F_1$ $f_{min}=f_{12}=3$. The new complex is (Eyes="brown"), the new examples are $x_2$, $x_7$, $x_8$ and the corresponding frequency table is $F_6$ (see Table VIII). Here $f_{12}=f_{min}=3$, consequently $r_6=((\text{Eyes}="\text{brown}")=>(\text{Class}="-"))$. The value $f_{12}$ in the frequency table $F_1$ will be put to zero.

### Table VIII. The frequency table $F_6$ (Eyes="brown")

<table>
<thead>
<tr>
<th></th>
<th>$A_1$</th>
<th>$A_2$</th>
<th>$A_3$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$v_1$</td>
<td>1/0</td>
<td>1/0</td>
<td>3</td>
</tr>
<tr>
<td>$v_2$</td>
<td>2</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>$v_3$</td>
<td>*</td>
<td>2</td>
<td>*</td>
</tr>
</tbody>
</table>

**Step 8:** The new minimal value in $F_1$ is $f_{min}=f_{12}=4$, the new complex is (Hair="blond") and the new examples for learning are $x_1$, $x_5$, $x_6$, $x_8$, the corresponding frequency table is $F_7$ (see Table IX).

### Table IX. The frequency table $F_7$ (Hair="blond")

<table>
<thead>
<tr>
<th></th>
<th>$A_1$</th>
<th>$A_2$</th>
<th>$A_3$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$v_1$</td>
<td>2/0</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>$v_2$</td>
<td>2</td>
<td>2/0</td>
<td>2</td>
</tr>
<tr>
<td>$v_3$</td>
<td>*</td>
<td>*</td>
<td>*</td>
</tr>
</tbody>
</table>

**Step 9:** The minimal value in $F_7$ is $f_{min}=f_{12}=2$, the corresponding complex is (Hair="blond" & Height="tall"), the frequency table is $F_8$ (see Table X) and the new $f_{min}=f_{13}=1$ in $F_8$. Consequently: $r_7 = ((\text{Hair}="\text{blond}" & \text{Height}="\text{tall}" & \text{Eyes}="\text{blue}")=>(\text{Class}="+"))$. The value $f_{13}$ in the frequency table $F_8$ and after that the value $f_{12}$ in the frequency table $F_7$ will be put to zero.

### Table X. The frequency table $F_8$ (Hair="blond"&Height="tall")

<table>
<thead>
<tr>
<th></th>
<th>$A_1$</th>
<th>$A_2$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$v_1$</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>$v_2$</td>
<td>1/0</td>
<td>1</td>
</tr>
<tr>
<td>$v_3$</td>
<td>*</td>
<td>*</td>
</tr>
</tbody>
</table>

**Step 10:** The new minimal value in $F_7$ is $f_{min}=f_{13}=2$ and the new frequency table is $F_9$ (see Table XI). Here $f_{13}=f_{min}=2$ and consequently $r_8 = ((\text{Hair}="\text{blond}" & \text{Eyes}="\text{blue}")=>(\text{Class}="+"))$. The value $f_{13}$ in the frequency table $F_7$ will be put to zero. In $F_7$ there is no $f_{min}=0$, so $f_{13}$ in $F_1$ will be put to zero.
Step 11: The new minimal value in the frequency table $F_1$ is $f_{\text{min}}=f_{12}=5$, the corresponding complex is $(\text{Height}=\text{tall})$, the examples are $x_2$, $x_3$, $x_5$, $x_6$, $x_7$ and the new frequency table is $F_{10}$ (see Table XII).

Table XII. The frequency table $F_{10}$ (Height=“tall”)

<table>
<thead>
<tr>
<th></th>
<th>A₁</th>
<th>A₂</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>v₁</td>
<td>2 0</td>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>v₂</td>
<td>1 0</td>
<td>2 0</td>
<td>2</td>
</tr>
<tr>
<td>v₃</td>
<td>2 0</td>
<td>*</td>
<td>*</td>
</tr>
</tbody>
</table>

Step 12: The minimal value of $F_{10}$ is $f_{\text{min}}=f_{13}=3$. The new complex $(\text{Height}=\text{tall}& \text{Eyes}=\text{blue})$ and the corresponding frequency table $F_{11}$ (see Table XIII) give no new rule.

Table XIII. The frequency table $F_{11}$ (Height=“tall”&Eyes=“blue”)

<table>
<thead>
<tr>
<th></th>
<th>A₁</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>v₁</td>
<td>1 0</td>
<td>1</td>
</tr>
<tr>
<td>v₂</td>
<td>1 0</td>
<td>2</td>
</tr>
<tr>
<td>v₃</td>
<td>1 0</td>
<td>*</td>
</tr>
</tbody>
</table>

In the table $F_{10}$ no new $f_{\text{min}}\neq 0$ can be found, therefore in $F_1$ the value $f_{12}$ will be put to zero.

Step 13: The complex (Eyes=“blue”) will be generated on the base of $f_{\text{min}}=f_{13}=5$ in $F_1$. The corresponding frequency table is $F_{12}$ (see Table XIV). The examples belong to both of the classes and the new minimal value cannot be found. Consequently the frequency $f_{13}$ in $F_1$ can be put to zero.

Table XIV. The frequency table $F_{12}$ (Eyes=“blue”)

<table>
<thead>
<tr>
<th></th>
<th>A₁</th>
<th>A₂</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>v₁</td>
<td>2 0</td>
<td>2 0</td>
<td>2</td>
</tr>
<tr>
<td>v₂</td>
<td>3 0</td>
<td>1 0</td>
<td>3</td>
</tr>
<tr>
<td>v₃</td>
<td>*</td>
<td>2 0</td>
<td>*</td>
</tr>
</tbody>
</table>

Now the concept description is ready because in the frequency table $F_1$ there is no minimal value different from zero.

So altogether eight rules were generated by the algorithm MONSIL:

$r_1=((\text{Hair}=\text{red})=>(\text{Class}=\text{+}));$
$r_2=((\text{Height}=\text{short}&\text{Hair}=\text{dark})=>(\text{Class}=\text{-}));$
$r_3=((\text{Height}=\text{short}&\text{Eyes}=\text{brown})=>(\text{Class}=\text{-}));$
$r_4=((\text{Height}=\text{short}&\text{Hair}=\text{blond}&\text{Eyes}=\text{blue})=>(\text{Class}=\text{+}));$
$r_5=((\text{Hair}=\text{dark})=>(\text{Class}=\text{+}));$
$r_6=((\text{Eyes}=\text{brown})=>(\text{Class}=\text{-}));$
$r_7=((\text{Height}=\text{tall}&\text{Hair}=\text{blond}&\text{Eyes}=\text{blue})=>(\text{Class}=\text{+}));$
$r_8=((\text{Hair}=\text{blond}&\text{Eyes}=\text{blue})=>(\text{Class}=\text{+}));$

Now we apply the second procedure for lessening a number of rules. If there are two rules $r_i$ and $r_j$ in the description so that: $r_i \& C_{\text{om}} \subseteq C_{\text{om}}$, then the rule $r_j$ can be excluded from the description. If any example is covered by such a rule $r_i$ then it is also covered by the rule $r_j$.

So for our example the rules $r_2$, $r_3$, $r_4$ and $r_7$ can be excluded from our description:

rule $r_1$ covers $x_3$ of Class “+”;
rule $r_2$ covers $x_5$ and $x_6$ of Class “-”;  
rule $r_3$ covers $x_3$, $x_6$ and $x_9$ of Class “-”;  
rule $r_4$ covers $x_1$, $x_7$ and $x_8$ of Class “+”.

The resulting description is complete and consistent.

It is easy to check that rules $r_1$, $r_2$, $r_3$ correspond to the ID3 rules, but the rule $r_7= ((\text{Eyes}=\text{brown})=>(\text{Class}=\text{+}))$ is simpler than ID3 rule $ ((\text{Hair}=\text{blond}&\text{Eyes}=\text{brown})=>(\text{Class}=\text{-}))$. It covers $x_7$ which is already covered by rule $r_5$ (overlapping). ID3 covers objects only once.

E. The second example

If we use initial data table with different order of attributes (columns): $A_2$ (Hair) – $A_1$ (Eyes) – $A_3$ (Height), then the search tree traversed by the algorithm is different (stricken-through text shows the places where zeros “brought down” from upper frequency table prevent entering corresponding (redundant) branches of the search tree):

Hair="red" (r1)
Hair="dark" (r2)
Eyes="brown" (r3)
Height="short"
 &Hair="dark"
 &Eyes="brown"
 &Hair="blond"
 &Eyes="brown"
 &Eyes="blue" (r4)
 &Eyes="blue"
 &Hair="dark"
 &Hair="blond"

Hair="blond"
 &Eyes="brown"
 &Height="short"
 &Eyes="blue" (r5)
 &Height="tall"
 &Eyes="blue"
 &Eyes="brown"

Eyes="blue"
 &Hair="dark"
 &Hair="red"
 &Hair="blond"
 &Height="short"
 &Height="tall"
 &Hair="dark"
As a result we get five rules:

\[ r_1 = ((\text{Hair} = \text{"red"}) \Rightarrow (\text{Class} = \text{"+"})); \]
\[ r_2 = ((\text{Hair} = \text{"dark"}) \Rightarrow (\text{Class} = \text{"-"})); \]
\[ r_3 = ((\text{Eyes} = \text{"brown"}) \Rightarrow (\text{Class} = \text{"-"})); \]
\[ r_4 = ((\text{Height} = \text{"short"} \& \text{Hair} = \text{"blond"} \& \text{Eyes} = \text{"blue"}) \Rightarrow (\text{Class} = \text{"+"})); \]
\[ r_5 = ((\text{Hair} = \text{"blond"} \& \text{Eyes} = \text{"blue"}) \Rightarrow (\text{Class} = \text{"+"})). \]

One of them is redundant: \( r_4 \) is a specification of \( r_5 \). The example showed that the result of the algorithm MONSIL depends on used order of attributes' values. But after using the second procedure for lessening the number of rules we always get the same result. For our example it is four rules as in case of previous example:

- rule \( r_1 \) covers \( x_1 \) of Class \( \text{"+"} \);
- rule \( r_2 \) covers \( x_3, x_4, x_7 \) of Class \( \text{"-"} \);
- rule \( r_3 \) covers \( x_2, x_3, x_7, x_8 \) of Class \( \text{"+"} \);
- rule \( r_5 \) covers \( x_1 \) and \( x_6 \) of Class \( \text{"+"} \).

### IV. Effectiveness of MONSIL

D. Michie has described in [5] an experiment in the Turing Institute comparing different algorithms of inductive learning. We use a similar King-Rook-King task to compare the effectiveness of the algorithms MONSIL and ID3.

D. Michie took a set of random positions with three pieces on a chess-board - white king, white rook and black king as a set of objects. The position of each piece on the board is described by two attributes. In some positions white’s move is allowed by chess laws, in some positions not. So, two classes can be distinguished. The possible number of different positions is \( 64^3 = 262144 \).

In our experiment three similar training suites consist of five sets of positions which were randomly generated as training data examples and two test data suites consist of two sets of examples which were randomly generated for testing. All sets of positions are generated independently that means bigger sets may not consist of smaller sets and the same size sets in different suites are not the same.

We have split our test scenario into two stages. In both stages we have several training data example sets and one testing set. All rules found by both learning algorithms for every training data example set are tested separately. The speed of generating rules, the number of rules and the exactness of predicting were estimated.

**In the first stage** we used two training data sets from each (three) training suite, first one containing 1000 examples and second one containing 2000 examples. All (2x3) found rule sets from each training suite were tested with one set of 200 positions.

**In the second stage** we used the same two training data sets from each training suite, which were used already in the first stage. In addition, we used three training-data sets from each training suite, where accordingly 3000, 4000 and 8000 examples were present. The size of the testing set was 400 positions.

In our experiment the test scenario was executed two times. Only the test data suite was replaced on the second time. In both cases the same training suites were used. In the first execution, test data suite 1 was used and in the second run we used test data suite 2.

The results of the experiments with both MONSIL and ID3 base algorithm are presented in the five following tables and illustrated with four figures. Table XV holds the average speed of generating rules, Tables XVI, XVII and XVIII hold the average exactness of predictions and Table XIX holds the average number of found rules. Figure 1 shows trends of growth of both algorithms’ average execution times while the learning examples were growing. Figure 2 shows the ratio between MONSIL and ID3 algorithms’ average execution times. Figure 3 shows trends of growth of both algorithms’ average number of rules while the learning examples were growing. Figure 4 shows the ratio between MONSIL and ID3 algorithms’ average number of rules. (Both algorithms are implemented in Java. The computer used in the experiment was Pentium M 2.0GHz.)

We notice that the MONSIL algorithm is more exact in classification and not very much slower than the ID3 algorithm regardless of fact that it extracts much more rules.

* In the Table XIX procedure for lessening a number of rules was not used.

Fig. 3. Average number of rules
V. ADVANTAGES AND DISADVANTAGES OF MONSIL

We saw in chapter III.D that it can be happen that two or more rules cover the same object. Such a situation is called an overlapping.

“Classical” algorithms do not take this situation into account. If a rule is added to the description, then corresponding examples will not be taken into consideration during generating next rules.

The use of frequency table technique allows to overcome this disadvantage. So, in case of overlapping the rule will be generated on the basis of larger set of examples than “classical” algorithms do. In the example of the section III.D the learning example $x_i$ is covered by complexes of the rules $r_k$ and $r_{k'}$.

It is easy to discover the contradictory examples in MONSIL, i.e. the situation where the objects with identical descriptions (complexes) belong to different classes. It is done as follows: if we have reached to such node of a search tree, where it is not possible to make the next extract (all the attributes are used already, but objects still belong to different classes), then we can say that these examples are contradictory.

In the case of large sets of examples algorithm MONSIL is quite quick (as we could see in the previous section). Most of its speed comes thanks to the circumstance that a frequency table allows to estimate the conformity of attributes in a very simple way. Using the frequency table method allows to reduce necessary memory space dramatically in real applications as well.

The other difficult problem - noise - can be taken into account by different pruning techniques. Those techniques allow to choose different parameters and values of them. In our examples and experiments presented in the paper we did not use any pruning techniques.

MONSIL extracts a lot of classification rules. The exclusion of excessive rules from the description takes some additional time proportional to the square of the rules number.

VI. POSSIBLE MODIFICATIONS OF MONSIL USING PREPRUNING TECHNIQUES

The completeness and consistency of a description are very important in the algorithm MONSIL, but it is much more important in the practical systems of learning from examples that as many as possible objects will be classified exactly. Usually, learning examples presented to the system form only a small part from whole possible example set and there is often different level of noise in them. A consistent and complete description found for the set of examples does not have to be the best one. Giving up those strict requirements we can often find rules that guarantee exact classification on many more objects from the same expert field.

The main technique to facilitate work with noisy and large sets of examples is pruning. It can reduce the size of the decision tree or of the set of examples, making at the same time the prediction more exact. If by generating the concept description the requirements of consistency and completeness are given up, then we are dealing with pre-pruning. If changes affecting completeness and consistency are made in an already generated description, then such a technique is called post-pruning. Pre-pruning techniques are unique for different algorithms while post-pruning techniques are similar.

In the following we present some pre-pruning techniques one can use in our algorithm MONSIL. There are six different techniques of pre-pruning based on following indicators:

1) Class frequency,
2) Rule weight,
3) Frequency threshold,
4) Deviation,
5) Rule length,
6) Common rule.

Class frequency. Class frequency $P_f$ the indicates percentage of examples of the current majority class in the subset of examples

$$P_f = \frac{N_{m}}{N} \times 100\%$$

where $N_{m}=\max |E|$ - number of examples in the majority class.

Class frequency threshold $P'_f$ sets a condition, that a classification rule is only then added to the description if $P_f > P'_f$. Using the threshold of class frequencies reduces the risk of over-specification created by the noise. It is also possible that the size of description and time spent to create it on the computer diminishes, because the rules are more general and not so many fractured frequency tables have to be calculated. If pruning is not necessary, then $P'_f=100\%$.

Rule weight. Rule weight $P_w$ indicates a percentage of examples covered by complex $C_{m}$ in whole set of examples

$$P_w = \frac{N_{com}}{N} \times 100\%$$

If the weight $P_w$ for a complex is less than a threshold $P'_w$, then all corresponding elements of the frequency table will be
put to zero. It means also that this rule will not be added to the description D. If \( P'_{m}=0 \), then no pruning takes place.

**Frequency threshold.** If elements of the frequency table are less than the frequency threshold \( P'S \) then there will be no search for new complexes. It means that after creating the frequency table the command “IF \( f_k<P'S \) THEN Let \( f_k=0 \)” would be executed. If \( P'S=1 \), then no pruning takes place.

**Deviation.** Deviation \( P_d \) indicates the number of examples that are covered by complex but do not belong to the corresponding majority class. If the deviation in a set of examples extracted by the complex Com is less than the deviation threshold \( P'_d \), then a rule \( r=(\text{Com},c) \) can be added into description D. If the deviation threshold is \( P'_d=0 \), then rules will not be pruned.

**Rule length.** Rule length \( P_l \) is the number of selectors \( \text{Sel}_j \) not equal to the set of values of the attribute \( t_j \). If the rule length is less than the threshold of the minimal rule length \( P'_l \), then the rule will not be added into the description D. Using the minimal rule length threshold allows to reduce the risk of overgeneralization caused by the small size of the set of examples or by the lack of negative examples. If \( P'_l=0 \), then no pruning takes place.

If the rule length increases over the threshold of the maximal rule length \( P'_m \) then the corresponding rule will not be added to the description D and new frequency table will not be calculated. Using the maximal rule length threshold allows to reduce the risk of overspecification. If \( P'_m=M \), then all possible rules will be generated.

**Common rule.** All rules which map to the majority class \( C_m \) will not be produced by generating the concept description. Instead of it a rule \( r=(\text{Com},c) \) will be added, where \( \text{Com}=(A_1,...,A_M) \). If no rule exists that covers object that ought to be classified then it will be classified as an object which belongs to the majority class. So, using the common rule we assume that an unknown object belongs most probably to the majority class.

**VIII. CONCLUSION**

This paper described a monotone system approach for inductive learning. A new learning algorithm that rests on the theory of monotone systems is presented and discussed. A comparison of the effectiveness of the algorithm with ID3 on the well-known King-Rook-King task by D. Michie was presented. It showed that the base algorithm MONSEIL produces much more rules than ID3, but it is more exact in classification and at the same time it is not very much slower than ID3. We can say also that using several pruning techniques described in the paper we can do it more effective. The main goal of the paper was presentation of monotone systems approach for inductive learning, a base algorithm MONSA and its development - the algorithm MONSIL.
